

Agentic Research OS — what it ends up like

One git-backed ledger. A fleet of background agents. This chat is the dashboard.

git is the message bus

■ auto-merge on green CI

■ human-gated (you approve)

■ notes / low-risk

Liveness — how agents don't fall asleep

Containers are ephemeral. Agents are resumable + externally woken, never long-lived.

1. Cron heartbeat

GitHub Actions wakes each agent on a schedule (compute */5 min, literature weekly).

A dead container doesn't matter — the next tick spins up a fresh one.

wake → read ledger → claim → work → commit → die

2. Event wake-ups

PR comments, CI results, pushes wake the right agent instantly via webhooks —

bursts handled between heartbeats, not held until the next tick.

3. Self-scheduled check-ins

For 'come back in an hour and re-verify', an agent re-arms a timer before its container dies.

state is durable

session = disposable
ledger = permanent

Why a fresh wake-up never loses work:

**ALL STATE LIVES IN THE LEDGER,
NOT IN THE SESSION.**

**Boot → read ledger → see ready/claimed/stale → resume.
Stale claims (died mid-task) auto-release after 15 min.**

Where it lives & the rollout

A 4th pillar in Standards, consumed by MIWN. Built generic from day one.

Rollout — each phase small, ships value

- 1 Scaffold the pillar (schema + autonomy + dashboard). No behavior yet.
- 2 Compute agent → absorbs the manual rerun scripts. Proves the loop.
- 3 Figure agent (gate already done).
- 4 Write proof + reference gates, then proof & literature agents.
- 5 Writing/QA agent + scheduled morning digest.
- 6 Migrate REZN proofs/manuscript into MIWN (consolidation).
